Introduction

The Problem

The Solution

Case Study

Closing

- figures are based on 3.5M simulations
- each simulation generates data, removes values, applies strategy, then runs a model
- parameters of interest are missing regime and correction strategy
- metrics of interest are coefficient values and model performance
- details in conference.scipy.org/proceedings/scipy2018

Introduction

The Problem

The Solution

Case Study

Closing

- open code and data for reproducibility (but start small)
- everything at github.com/deniederhut/safe-handling-instructions-for-missing-data
- requires Python with `impyute`, `jupyter`, `numpy`, `pandas`, `scikit-learn`, `scipy.stats`

a very common occurrence...

joris	3	7.0

Table: Results of a hypothetical pie eating contest, from the SciPy 2018 Pandas tutorial

Common examples include:

- nonobserved population segments
- participants who drop out from longitudinal studies
- sensors that malfunction and stop reporting
- network problems that cause data loss in transit

...that (silently) destroys everything you love...

About

Introduction

The Problem

The Solution

Case Study

Closing

- Missing Completely At Random (MCAR)
a stochastic process is determining missingness

$$P(m_x) = f()$$

- Missing At Random (MAR)
a deterministic but noisy process removes data based on other data

$$P(m_x) = f(y)$$

- Missing Not At Random (MNAR)
a deterministic but noisy process removes data based on itself

$$P(m_x) = f(x)$$

...some of which are worse than others

Figure: Dr. Ben Inglis, Fixer of Acquisitions

- track the provenance of your data
- identify the step(s) where missingness appears
- your research design might be hiding missed observations

1. collect auxiliary features

SHIMD

Dillon
Niederhut
@ dillonnieder-
hut

About

Introduction

The Problem

The Solution

Case Study

Closing

These are variables that are known to be correlated with some given feature. Examples include:

primary	auxiliary
income	education, zip code
temperature	time, humidity
crop yield	rainfall, fertilizer

2. establish your regime

This does two things for you:

0. it lets you know whether listwise deletion is an option
 1. it hints at strategies for fixing your acquisition
- depending on your data collection method and the quality of your provenance data, you might be able to recover these post-hoc

3. use a modern ML technique

SHIMD

About

Introduction

The Problem

The Solution

Case Study

Closing

Create any derivative features that you'll be using in your model first. Then, run one of the following,

- Multiple Overimputation (MO)
- Multiple Imputations by Chained Equations (MICE)
- MissForest

Generate 5-10 imputed datasets.

4. run your analysis

SHIMD

About

Introduction

The Problem

The Solution

Case Study

Closing

The same way you normally would, just 5-10 times, so plan for extra compute time. Keep an eye on the parameters coming out of the model, and flag any that are unstable.

5. report all the things

SHIMD

Dillon
Niederhut
@ dillonnieder-
hut

About

Introduction

The Problem

The Solution

Case Study

Closing

At a minimum, every paper should include:

- the percentage of observations that had missing values
- the missingness regime (including correlation statistics)
- the imputation technique used (even if it is deletion!)
- model parameters averaged over the imputed data
- descriptive statistics for any unstable parameters

About

Introduction

The Problem

The Solution

Case Study

Closing

- 70% of observations had at least one missing value
- data were MAR, with strong correlations ($r > 0.4$) between missingness, meat quality, salsa quality, and target
- 5 datasets were imputed using implementation of Expectation Maximization algorithm from `impyute`
- averaged coefficients were:

meat	0.44
salsa	0.18
cost	0.11
